OBJECTIVE

To establish the prevalence of delirium in a general intensive care unit and to identify associated factors, clinical expression and the influence on outcomes.

METHODS

This was a prospective cohort study in a medical surgical intensive care unit. The Richmond Agitation-Sedation Scale and Confusion Assessment Method for the Intensive Care Unit were used daily to identify delirium in mechanically ventilated patients.

RESULTS

In this series, delirium prevalence was 80% (N = 184 delirious patients out of 230 patients). The... [CONTINUE](#)
